First-recorded, experimental, evidence-based approach (for trying to find the truth)

First-recorded, experimental, evidence-based approach (for trying to find the truth)

36 Then Gideon said to God, “If you will save
Israel by my hand, as you have
said, **37** behold, I am laying a fleece of wool
on the threshing floor. If there is dew on the
fleece alone, and it is dry on all the ground,
then I shall know that you will save Israel by
my hand, as you have said.”**38** And it was so.
When he rose early next morning and
squeezed the fleece, he wrung enough dew
from the fleece to fill a bowl with water[39].

Type 2 diabetes and risk of hospital admission or death for chronic liver diseases

Sarah H. Wild[1,*], Joanne R. Morling[1], David A. McAllister[1], Jan Kerssens[2], Colin Fischbacher[2], Julie Parkes[3], Paul J. Roderick[4], Naveed Sattar[5], Christopher D. Byrne[6,7], on behalf of the Scottish and Southampton Diabetes and Liver Disease Group, and the Scottish Diabetes Research Network Epidemiology Group[†]

and sex modified the association between T2DM and NAFLD. We suggest that there may be a role for targeted case finding of CLD and appropriate intervention in high risk populations including people with T2DM. The increasing global prevalence of T2DM can be expected to result in an increasing burden of all CLDs.

Not routine screening, but vigilance for chronic liver disease in patients with type 2 diabetes

Vincent Wai-Sun Wong[1,*], Naga Chalasani[2,*]

for NAFLD) at this time. We encourage health care providers taking care of diabetic patients to be vigilant for any signs and symptoms of chronic liver disease and refer the patients for further assessment and management.

Table 1. Wilson and Jungner classic screening criteria [16].

Factors	Criteria
Disease	The condition sought should be an important health problem.
	There should be a recognized latent or early symptomatic stage.
	The natural history of the condition, including development from latent to declared disease, should be adequately understood.
Setting	Facilities for diagnosis and treatment should be available.
Diagnosis	There should be a suitable test or examination.
	The test should be acceptable to the population.
	Case finding should be a continuing process and not a "once and for all" project.
Treatment	There should be an accepted treatment for patients with recognized disease.
	There should be an agreed policy on whom to treat as patients.
Cost-effectiveness	The cost of case finding (including diagnosis and treatment of patients diagnosed) should be economically balanced in relation to possible expenditure on medical care as a whole.

EASL EUROPEAN ASSOCIATION FOR THE STUDY OF THE LIVER | JOURNAL OF HEPATOLOGY

A position statement on NAFLD/NASH based on the EASL 2009 special conference☆

Vlad Ratziu[a], Stefano Bellentani[b,*], Helena Cortez-Pinto[c], Chris Day[d], Giulio Marchesini[e]

Diagnostic strategies for NASH

Many individuals at risk for NAFLD/NASH seek medical attention outside the Hepatology clinics and therefore it is important to establish whether and in what settings screening or case finding [141] for NASH is deemed necessary (see "Case finding"). Conversely, when patients with suspected NAFLD/NASH are addressed for hepatological investigations, the procedures to be performed need to be need to be defined on an individualized basis (see "Individual diagnostic strategies in clinical practice"), in particular the indications for liver biopsy.

Case finding

Screening or case finding of NASH [141] aims at diagnosing advanced liver disease, defined as NASH with bridging fibrosis or cirrhosis. Beyond the prognostic information it provides this may also change patient management including specific monitoring strategies, a stricter enforcement of diet and lifestyle measures, or the use of liver-targeted pharmacologic therapy.

Premises:

(1) In the general population, there are currently insufficient data on the prevalence of NASH, NASH-related mortality

fibrosis. In patients with both increased ALT anc
ultrasound (at higher risk for advanced liver dise
#3), liver biopsy could be the first-line procedure
sive independent validation of non-invasive meth
available.

3. Patients with chronic liver diseases other than N/
screened for metabolic risk factors, IR, and steat
sound. If all these are present, we suggest that
be performed to assess concurrent NAFLD, as c
invasive methods in patients with concurrent li
are lacking.
4. During elective surgical procedures, such as anti
gery (high risk of NASH and of unsuspected cirrho
lecystectomy (shared risk factors between
cholelithiasis), we suggest that a liver biopsy be

Clinical Practice Guidelines

EASL JOURNAL OF HEPATOLOGY

EASL–EASD–EASO Clinical Practice Guidelines for the management of non-alcoholic fatty liver disease☆

European Association for the Study of the Liver (EASL)*, European Association for the Study of Diabetes (EASD) and European Association for the Study of Obesity (EASO)

Introduction

The Clinical Practice Guidelines propose recommendations for the diagnosis, treatment and follow-up of non-alcoholic fatty liver disease (NAFLD) patients and are the product of a joint effort by the European Association for the Study of the Liver (EASL), European Association for the Study of Diabetes (EASD) and European Association for the Study of Obesity (EASO). They update a position statement based on the 2009 EASL Special Conference [1].

The data have been retrieved by an extensive PubMed search up to April 2015. The final statements are graded according to the level of evidence and strength of recommendation, which are adjustable to local regulations and/or team capacities (Table 1) [2]. In particular, screening for NAFLD in the population at risk should be in the context of the available resources, considering the burden for the national health care systems and the currently limited effective treatments. The document is intended both for practical use and for advancing the research and knowledge of NAFLD in adults, with specific reference to paediatric NAFLD whenever necessary. The final purpose is to improve patient care and awareness of the importance of NAFLD, and to assist stakeholders in the decision-making process by providing evidence-based data, which also takes into consideration the burden of clinical management for the healthcare system.

Definition

NAFLD is characterised by excessive hepatic fat accumulation, associated with insulin resistance (IR), and defined by the presence of steatosis in >5% of hepatocytes according to histological analysis or by a proton density fat fraction (providing a rough estimation of the volume fraction of fatty material in the liver) >5.6% assessed by proton magnetic resonance spectroscopy (^{1}H-MRS) or quantitative fat/water selective magnetic resonance imaging (MRI). NAFLD includes two pathologically distinct conditions with different prognoses: non-alcoholic fatty liver (NAFL) and non-alcoholic steatohepatitis (NASH); the latter covers a wide spectrum of disease severity, including fibrosis, cirrhosis and hepatocellular carcinoma (HCC) (Table 2).

The diagnosis of NAFLD requires the exclusion of both secondary causes and of a daily alcohol consumption ⩾30 g for men and ⩾20 g for women [1]. Alcohol consumption above these limits indicates alcoholic liver disease. The relationship between alcohol and liver injury depends on several cofactors (type of alcoholic beverage, drinking patterns, duration of exposure, individual/genetic susceptibility), rendering simple quantitative thresholds at least partly arbitrary. Specifically, patients consuming moderate amounts of alcohol may be still predisposed to NAFLD if they have metabolic risk factors. Of note, the overall impact of metabolic risk factors on the occurrence of steatosis appears to be higher than that of alcohol in these patients [3]. The definitive diagnosis of NASH requires a liver biopsy.

Recommendations

- All individuals with steatosis should be screened for features of MetS, independent of liver enzymes. All individuals with persistently abnormal liver enzymes should be screened for NAFLD, because NAFLD is the main reason for unexpectedly elevated liver enzymes (**A1**)
- In subjects with obesity or MetS, screening for NAFLD by liver enzymes and/or ultrasound should be part of routine work-up. In high risk individuals (age >50 years, T2DM, MetS) case finding of advanced disease (i.e. NASH with fibrosis) is advisable (**A2**)
